   Problem 2 — Regularization
        1. Loss function
       2. Compute and regularization
       3. Comparison
       4. Change λ
   Problem 3 — Feature Selection
        1. Lesser variables
       2 A better model
   Problem 4 — Gradient Descent
       Cost and gradient functions
       Datasets
           Parameters
           Run
           Compare with theta(s)=0
```

#### ▶ 详细信息

In this problem, you will attempt to study the relationship between average global temperature and several other factors. The file climate\_change\_1.csv contains climate data from May 1983 to December 2008. The available variables include:

Year: the observation year.

Month: the observation month.

Temp: the difference in degrees Celsius between the average global temperature in that period and a reference value. This data comes from the <u>Climatic Research Unit at the University of East Anglia</u>.

CO2 , N2O , CH4 , CFC.11 , CFC.12 : atmospheric concentrations of carbon dioxide  $(CO_2)$ , nitrous oxide  $(N_2O)$ , methane  $(CH_4)$ , trichlorofluoromethane  $(CCl_3F$ commonly referred to as CFC-11) and dichlorodifluoromethane  $(CCl_2F_2)$ ; commonly referred to as CFC-12, respectively. This data comes from the <u>ESRL/NOAA Global Monitoring Division</u>.

CO2, N2O and CH4 are expressed in ppmv (parts per million by volume -- i.e., 397 ppmv of CO2 means that CO2 constitutes 397 millionths of the total volume of the atmosphere)

CFC.11 and CFC.12 are expressed in ppbv (parts per billion by volume).

Aeroso1s: the mean stratospheric aerosol optical depth at 550 nm. This variable is linked to volcanoes, as volcanic eruptions result in new particles being added to the atmosphere, which affect how much of the sun's energy is reflected back into space. This data is from the <u>Godard Institute for Space Studies at NASA</u>.

TSI: the total solar irradiance (TSI) in W/m2 (the rate at which the sun's energy is deposited per unit area). Due to sunspots and other solar phenomena, the amount of energy that is given off by the sun varies substantially with time. This data is from the SOLARIS-HEPPA project website.

MET: multivariate El Nino Southern Oscillation index (MEI), a measure of the strength of the El Nino/La Nina-Southern Oscillation (a weather effect in the Pacific Ocean that affects global temperatures). This data comes from the ESRL/NOAA Physical Sciences Division.

# **Preparation**

### Import data

```
import pandas as pd
df1 = pd.read_csv('./data/climate_change_1.csv')
df2 = pd.read_csv('./data/climate_change_2.csv')
```

# **Exploration and cleaning**

### **Data structure**

```
1 dfl.head().round()
```

```
1  .dataframe tbody tr th {
2    vertical-align: top;
3  }
4  .dataframe thead th {
6    text-align: right;
7  }
```

	Year	Month	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	Temp
0	1983	5	3.0	346.0	1639.0	304.0	191.0	350.0	1366.0	0.0	0.0
1	1983	6	2.0	346.0	1634.0	304.0	192.0	352.0	1366.0	0.0	0.0
2	1983	7	2.0	344.0	1633.0	304.0	193.0	354.0	1366.0	0.0	0.0
3	1983	8	1.0	342.0	1631.0	304.0	194.0	356.0	1366.0	0.0	0.0
4	1983	9	0.0	340.0	1648.0	304.0	194.0	357.0	1366.0	0.0	0.0

```
1 df2.head().round(2)
```

```
dataframe tbody tr th {
    vertical-align: top;
}

dataframe thead th {
    text-align: right;
}
```

	Year	Month	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	NO	Temp
0	1983	5	2.56	345.96	1638.59	303.68	191.32	350.11	1366.10	0.09	2.64	0.11
1	1983	6	2.17	345.52	1633.71	303.75	192.06	351.85	1366.12	0.08	2.63	0.12
2	1983	7	1.74	344.15	1633.22	303.80	192.82	353.72	1366.28	0.07	2.63	0.14
3	1983	8	1.13	342.25	1631.35	303.84	193.60	355.63	1366.42	0.07	2.63	0.18
4	1983	9	0.43	340.17	1648.40	303.90	194.39	357.46	1366.23	0.06	2.65	0.15

# **Statistics**

The most significant difference is the variable NO. Then explore **basic statistics** with round three:

```
1 df1.describe().round(3)
```

```
1   .dataframe tbody tr th {
2    vertical-align: top;
3   }
4   .dataframe thead th {
6    text-align: right;
7   }
```

	Year	Month	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	Temp

### Missing data

```
1 df1.info()
```

```
1 df2.info()
```

No missing data were found, then continue.

# **Duplication**

```
print('Duplicated rows:', len(df1[df1.duplicated()]), ', then continue.')

Duplicated rows: 0 , then continue.
```

### **Outliers**

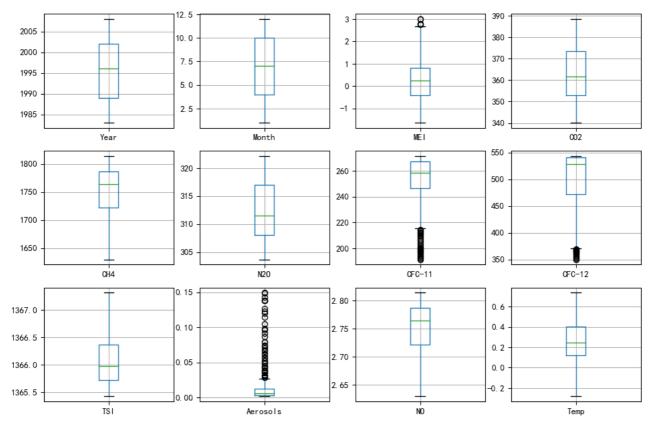

Conduct a boxploting to find out outliers in DF1 and DF2:

```
import sys
import seaborn as sns
import matplotlib.pyplot as plt
fig1 = plt.figure(figsize=(12,8), dpi=96)
for i in range(1, len(df1.columns) + 1):
    fig1.add_subplot(3, 4, i)
    df1.iloc[:, [i-1]].boxplot()

range(1, len(df2.columns) + 1)
```

```
1 | range(1, 13)
```

```
fig2 = plt.figure(figsize=(12,8), dpi=96)
for i in range(1, len(df2.columns) + 1):
fig2.add_subplot(3, 4, i)
df2.iloc[:, [i-1]].boxplot()
```

Check outliers:

```
1 | import ipywidgets as widgets
    z_slider = widgets.FloatSlider(
       value=2.9,
 4
        min=2,
        max=3.5,
       step=0.1,
 6
        description='Threshold:',
        disabled=False,
 8
 9
        continuous_update=True,
10
        orientation='horizontal',
11
       readout=True,
        readout_format='.1f',
12
13 )
14 z_slider
```

```
1 | FloatSlider(value=2.9, description='Threshold:', max=3.5, min=2.0, readout_format='.1f')
```

```
from scipy import stats
import numpy as np
z = np.abs(stats.zscore(df1['MEI']))
outlier_index = np.where(z > z_slider.value)[0]
print('Threshhold:', z_slider.value)
print('Index:', outlier_index)
print('Outlier:', [df1['MEI'][i] for i in outlier_index])
```

```
1 Threshhold: 2.9
2 Index: [171 172]
3 outlier: [3.00100000000003, 3.0]
```

Since rare outliers, ignore at preparation step and continue.

#### Correlation

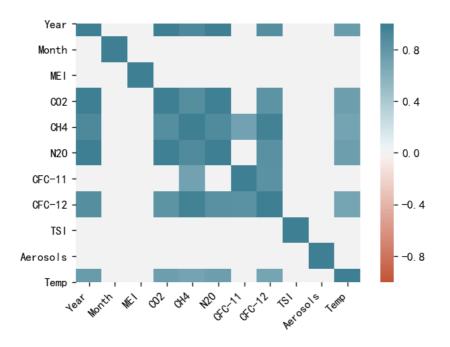

Find and plot highly correlated variables (r>0.6 in df1, plotting r>0.5):

```
1    corr = df1.corr()
2    high_corr = corr[np.abs(corr) > 0.5].fillna(0)
3    corr[np.abs(corr) > 0.6].fillna('')
```

```
1   .dataframe tbody tr th {
2    vertical-align: top;
3   }
4   
5   .dataframe thead th {
6    text-align: right;
7   }
```

	Year	Month	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	Temp
Year	1			0.985379	0.910563	0.99485		0.870067			0.755731
Month		1									
MEI			1								
CO2	0.985379			1	0.872253	0.981135		0.82321			0.748505
CH4	0.910563			0.872253	1	0.894409	0.713504	0.958237			0.699697
N20	0.99485			0.981135	0.894409	1		0.839295			0.743242
CFC-11					0.713504		1	0.831381			
CFC-12	0.870067			0.82321	0.958237	0.839295	0.831381	1			0.688944
TSI									1		
Aerosols										1	
Temp	0.755731			0.748505	0.699697	0.743242		0.688944			1

```
1 plt.figure(dpi=128)
 2 ax = sns.heatmap(
 3
    high_corr,
 4
       vmin=-1, vmax=1, center=0,
 5
      cmap=sns.diverging_palette(20, 220, n=200),
 6
      square=True
 7 )
 8 ax.set_xticklabels(
     ax.get_xticklabels(),
9
      rotation=45,
horizontalalignment='right'
10
11
12 );
```

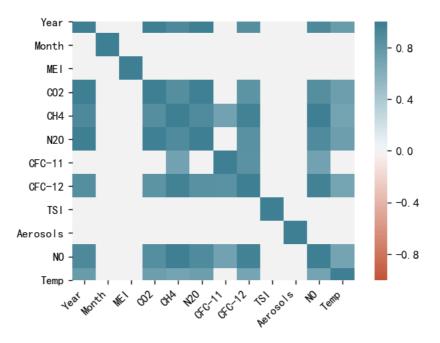

Similarly, correlation in df1:

```
corr = df2.corr()
high_corr = corr[np.abs(corr) > 0.5].fillna(0)
corr[np.abs(corr) > 0.6].fillna('')
```

```
1 .dataframe tbody tr th {
2    vertical-align: top;
3  }
4  
5    .dataframe thead th {
6    text-align: right;
7  }
```

	Year	Month	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	NO	Temp
Year	1			0.985379	0.910563	0.99485		0.870067			0.910563	0.755731
Month		1										
MEI			1

CH4	0.910563			0.872253	1	0.894409	0.713504	0.958237			1	0.699697
N20	0.99485			0.981135	0.894409	1		0.839295			0.894409	0.743242
CFC-11					0.713504		1	0.831381			0.713504	
CFC-12	0.870067			0.82321	0.958237	0.839295	0.831381	1			0.958237	0.688944
TSI									1			
Aerosols										1		
NO	0.910563			0.872253	1	0.894409	0.713504	0.958237			1	0.699697
Temp	0.755731			0.748505	0.699697	0.743242		0.688944			0.699697	1

```
plt.figure(dpi=128)
     ax = sns.heatmap(
 3
        high_corr,
 4
         \label{eq:vmin--1} \mbox{ vmin} = -1, \mbox{ vmax} = 1, \mbox{ center} = 0,
         cmap=sns.diverging_palette(20, 220, n=200),
         square=True
 7 )
 8 ax.set_xticklabels(
9
         ax.get_xticklabels(),
10
         rotation=45,
11
         horizontalalignment='right'
12 );
```

Potential redundant variables found, however, now the data is prepared for analyzing.

# Problem 1 — First Model

We are interested in how changes in these variables affect future temperatures, as well as how well these variables explain temperature changes so far. To do this, first read the dataset climate\_change\_1.csv into Python or Matlab.

Then, split the data into a training set, consisting of all the observations up to and including 2006, and a testing set consisting of the remaining years. A training set refers to the data that will be used to build the model, and a testing set refers to the data we will use to test our predictive ability.

After seeing the problem, your classmate Alice immediately argues that we can apply a linear regression model. Though being a little doubtful, you decide to have a try. To solve the linear regression problem, you recall the linear regression has a closed form solution:  $\theta = (X^T X)^{-1} X^T Y$ 

### Read and split

Though data have been prepared in section Data Preparation, dataset df1 has been imported again here following problem description.

### Read the dataset:

```
# loaded in exploration

# import pandas as pd
# df1 = pd.read_csv('../data/climate_change_1.csv').iloc[:,2:]
```

#### Split into training set and testing set:

```
# Df1 trainset
df1_train = df1[df1['Year'] <= 2006].iloc[:,2:]
# Check the result
df1_train.iloc[[0, 1,-2, -1],:]</pre>
```

```
dataframe tbody tr th {
   vertical-align: top;
}

dataframe thead th {
   text-align: right;
}
```

	MEI	CO2	CH4	N20	CFC-11	CFC-12	TSI	Aerosols	Temp

### 1. Closed form function

Implement a function closed\_form\_1 that computes this closed form solution given the features X, labels y (using Python or Matlab).

Given a pandas  ${\tt Dataframe}$ , the features X is the dataframe excluding taget y, then:

```
1 \mid import numpy as np \# matrix, vector, and linear algebra support
    from numpy.linalg import inv # matrix inversion
 4
   def closed_form_1(X: np.ndarray, y: np.ndarray) -> np.matrix:
 5
 6
 7
       To calculate OLS theta(s) given X, y in ndarrays.
 9
       Parameters:
10
        X: features, IV.
y: taget variable, DV.
11
12
13
      Return:
14
       theta: coefficients
15
16
17
       X = np.column_stack((np.ones(len(X)), X)) # add x0 = 1 to matrix X
18
19
       theta = inv(X.T @ X) @ X.T @ y
20
       #theta = theta[1:].reshape((1,10))
21
       return theta
23
24 def closed_form_df(df: pd.core.frame.DataFrame, column: int = 8) -> np.matrix:
25
26
       To calculate OLS theta(s) given data in a DataFrame.
27
28
       Parameters:
29
30
          df: a DataFrame of data including both IV X and DV y.
31
          column = 8: index number of clomn where DV y lies. The default value is 8.
32
33
       Return:
34
       theta: coefficients
35
36
37
       X = df.drop(df.columns[column], axis=1).to_numpy() # X: the features
38
39
       X = np.column_stack((np.ones(len(X)), X)) # add x0 = 1 to matrix X
40
       y = df.iloc[:, [column]].to_numpy(
41
       ) # y: the results, lower case to emphasize the difference
       theta = inv(X.T @ X) @ X.T @ y
42
       #theta = theta[1:].reshape((1,10))
43
44
       return theta
```

Test  $closed_form_1$  and  $closed_form_df$  on df1:

```
1 df1_train.drop(df1_train.columns[8], axis=1).head(3)
```

```
1 | .dataframe tbody tr th {
2
      vertical-align: top;
3 }
4

2	1.741	344.15	1633.22	303.795	192.818	353.725	1366.2850	0.0731

```
1 | # Given X, and y in numpy arrays
2  X = df1_train.drop(df1_train.columns[8], axis=1).to_numpy() # X: the features
                                                             # y: the results, lower case to emphasize the difference
3 y = df1_train.iloc[:, [8]].to_numpy()
4 | X_test = df1_test.drop(df1_train.columns[8], axis=1).to_numpy()
5 y_test = df1_test.iloc[:, [8]].to_numpy()
6 theta = closed_form_1(X, y)
7 theta.flatten()
```

```
1 array([-1.24594260e+02, 6.42053134e-02, 6.45735927e-03, 1.24041896e-04,
2
         -1.65280032e-02, -6.63048889e-03, 3.80810324e-03, 9.31410835e-02,
          -1.53761324e+00])
```

```
1  # Given a DataFrame
theta = closed_form_df(df1_train).reshape((1,9))
3 theta.flatten()
```

```
2
  -1.53761324e+00])
```

Using *scipy* to check the result:

```
1 | from sklearn.linear_model import LinearRegression as lm
   l=lm().fit(x, y)
3 1.coef_.flatten()
```

Works fine (some differences due to SVD used in sklearn.LinearRegression).

# 2. Fomula and R squre

Write down the mathematical formula for the linear model and evaluate the model R squre on the training set and the testing set.

```
1 df1_train.columns
```

```

```

# Formula of R-squred

R-squared measures model fitting and can be calculated as:  $R^2 = \frac{var(X\hat{\beta})}{var(y)} = \frac{\sum_{i=1}^n (\hat{y}_i - \bar{y})^2}{\sum_{i=1}^n (y_i - \bar{y})^2}$ 

```
1 def predict(X: np.ndarray, theta: np.ndarray) -> np.ndarray:
  3
         To predict y given \boldsymbol{x} and theta.
  4
  5
         Parameters:
  6
           X: features, IV.
theta: coefficients.
  8
  9
 10
 11
         Return:
 12
         y_hat: predicted value.
 13
 14
 15
         X = np.column_stack((np.ones(len(X)), X)) # add x0 = 1 to matrix X
 16
 17
         # theta = theta.reshape((1, len(theta)))
 18
         y_hat = np.sum(X @ theta, axis=1)
 19
         return (y_hat)
 20
```

Define a score function to calculate  $\mathbb{R}^2$ :

```
1 def score(y: np.ndarray, y_hat: np.ndarray) -> float:
2
3
      To calculate OLS R^2 given data in ndarrays.
4
      Parameters:
6
         y: actual labels.
8
         y_hat: predicted values.
9
10
11
      SST: R^2 caculated based on y and y_hat.
12
13
14
15
      mean = y.mean()
      TSS = np.sum(np.square(y_hat - mean))
16
      ESS = np.sum(np.square(y - mean))
18
      SST = TSS / ESS
     return SST
19
```

On training set:

```
1  X = df1_train.drop(df1_train.columns[8], axis=1).to_numpy()
2  y = df1_train.iloc[:, [8]].to_numpy()
3  rsquare_train = score(y, predict(x, closed_form_1(x, y)))
4  print("R2:", rsquare_train)
5  # Use *scipy* to check the result:
7  l=lm().fit(x, y)
8  print("R2 by scipy:", l.score(x, y))
```

```
1 R2: 0.7508932770388383
2 R2 by scipy: 0.7508932770523428
```

On testing set:

```
rsquare_test = score(y_test, predict(X_test, closed_form_1(X, y)))
print("R2:", rsquare_test)
```

```
1 R2: 0.22517701916249677
```

Works fine.

### **Evaluation**

Based on the formula above, R-squred can be applied in Python to evaluate previous model. On training set:  $\mathbb{R}^2$  is 0.75089, while on testing set,  $\mathbb{R}^2$  is 0.22518.

\*\*\* However, for a multi-variable linear model,  $R^2_{adjusted}$  may be a better indicator because the original  $R^2$  is sensitive to the number of features.

# 3. Significant variables

Which variables are significant in the model?

```
import statsmodels.api as sm

# set an alpha
alpha = 0.05

x2 = sm.add_constant(x)
1 = sm.ols(y, x2).fit()
```

```
pvalues = l.summary2().tables[1]['P>|t|']
labels = ['x0: constant'] + ["x" + str(i+1) + ": " + df1_train.columns[i] for i in range(len(df1_train.columns)-1)]
variables = pd.DataFrame(np.concatenate([pd.DataFrame(labels), pd.DataFrame(pvalues)], axis=1))
variables.columns = ['variable', 'pvalues']

# print significant variables
variables[variables.pvalues < alpha]</pre>
```

```
dataframe tbody tr th {
    vertical-align: top;
}

dataframe thead th {
    text-align: right;
}
```

	Variable	pvalues
0	x0: constant	1.43105e-09
1	x1: MEI	4.89889e-20
2	x2: CO2	0.00505252
5	x5: CFC-11	5.95729e-05
6	x6: CFC-12	0.00020972
7	x7: TSI	1.09594e-09
8	x8: Aerosols	5.41127e-12

That's to say, significant(alpha=0.05) varibles are:

```
1 | [i for i in variables[variables.pvalues < alpha].Variable.to_numpy()]
```

```
1  ['x0: constant',
2   'x1: MEI',
3   'x2: CO2',
4   'x5: CFC-11',
5   'x6: CFC-12',
6   'x7: TSI',
7   'x8: Aerosols']
```

# 4. Necessary conditions and application

Write down the necessary conditions for using the closed form solution. And you can apply it to the dataset climate\_change\_2.csv, explain the solution is unreasonable.

### **Necessary conditions**

 $X^TX$  must be invertible.

```
1 df2.head(3)
```

```
1   .dataframe tbody tr th {
2     vertical-align: top;

```

#### Why unreasonable:

Because  $X^TX$  is non-invertible.

According to Andrew NG,

When implementing the normal equation in octave we want to use the pinv function rather than [inv]. The 'pinv' function will give you a value of \theta\theta even if  $X^TX$  is not invertible.

If  $X^TX$  is noninvertible, the common causes might be having :

- Redundant features, where two features are very closely related (i.e. they are linearly dependent)
- Too many features (e.g. m ≤ n). In this case, delete some features or use "regularization" (to be explained in a later lesson).

Solutions to the above problems include deleting a feature that is linearly dependent with another or deleting one or more features when there are too many features.

# Problem 2 — Regularization

 $Regularization \ is \ a \ method \ to \ boost \ robustness \ of \ model, \ including \ L1 \ regularization \ and \ L\_2 \ regularization.$ 

### 1. Loss function

Please write down the loss function for linear model with L1 regularization, L2 regularization, respectively.

- L1, Lasso Regression:  $J\left(\theta\right)=\frac{1}{2m}[\sum\limits_{i=1}^{m}\left(h_{\theta}\left(x^{(i)}\right)-y^{(i)}\right)^{2}+\lambda\sum\limits_{j=1}^{n}|\theta_{j}|]$
- **L2, Ridge Regression:**  $J\left(\theta\right)=\frac{1}{2m}[\sum\limits_{i=1}^{m}\left(h_{\theta}\!\left(x^{(i)}\right)-y^{(i)}\right)^{2}+\lambda\sum\limits_{j=1}^{n}\theta_{j}^{2}]$

# 2. Compute and regularization

The closed form solution for linear model with L2 regularization:  $_{\theta} = (\mathbf{X^TX} + _{\lambda}\mathbf{I})^{-1}\mathbf{X^TY}$  where l is the identity matrix. Write a function closed\_form\_2 that computes this closed form solution given the features X, labels Y and the regularization parameter  $\lambda$  (using Python or Matlab).

```
def closed_form_2(X: np.ndarray, y: np.ndarray, lambd: float) -> np.ndarray:
        To calculate OLS theta(s) given X, y in ndarrays.
3
4
5
        Parameters:
           X: features, IV.
          y: taget variable, DV.
lambd: regularization parameter
8
9
10
       Return:
       theta: coefficients
12
13
14
15
        X = np.concatenate([np.ones((len(X), 1)), X], axis=1) # add x0 = 1 to matrix X
       I = np.identity(len(X[0]))
17
        theta = inv(X.T @ X + lambd * I) @ (X.T @ y)
18
        return theta
```

### 3. Comparison

Compare the two solutions in problem 1 and problem 2 and explain the reason why linear model with L2 regularization is robust. (using climate\_change\_1.csv)

```
1  X_train = dfl_train.drop(dfl_train.columns[8], axis=1).to_numpy()
2  y_train = dfl_train.iloc[:, [8]].to_numpy()
3  theta_0 = closed_form_1(X_train, y_train)
4  theta_0.flatten()
```

```
theta_2 = closed_form_2(x_train, y_train, 0.5)
theta_2.flatten()
```

```
1 array([-4.68953239e-03, 4.55768014e-02, 7.80443532e-03, 1.95701031e-04,

2 -1.64893727e-02, -6.38359095e-03, 3.74766007e-03, 1.44919104e-03,

3 -3.65599605e-01])
```

```
rsquare_test_theta_0 = score(y_test, predict(X_test, theta_0))
rsquare_test_theta_2 = score(y_test, predict(X_test, theta_2))
print("R2:", rsquare_test_theta_0, rsquare_test_theta_2)

1 R2: 0.22517701916249677 0.8022366128860432
```

Obviously, theta\_2, which is the result of ridge regression, is much better due to the lower effect of redundant variables.

### 4. Change λ

You can change the regularization parameter  $\lambda$  to get different solutions for this problem. Suppose we set  $\lambda$  = 10, 1, 0.1, 0.01, 0.001, and please evaluate the model  $R^2$  on the training set and the testing set.

```
1 from sklearn.metrics import mean_squared_error as mse
 3 # Define constants
 4 X_train = df1_train.drop(df1_train.columns[8], axis=1).to_numpy()
 5 y_train = df1_train.iloc[:, [8]].to_numpy()
 6  X_test = df1_test.drop(df1_test.columns[8], axis=1).to_numpy()
 7 y_test = df1_test.iloc[:, [8]].to_numpy()
 8 lambds = [10.00, 1.000, 0.10, 0.01, 0.001]
10 print("R scores comparison")
10 print( ).
11 # print(") Training R2
                         Training R2 Testing R2 Testing MSE")
Training R2 Testing R2")
13 for lambd in lambds:
      theta = closed_form_2(X_train, y_train, lambd)
       rsquare_train = score(y_train, predict(X_train, theta))
rsquare_test = score(y_test, predict(X_test, theta))
15
16
       # meanse = mse(y_test, predict(X_test, theta))
# print(lambd, " ", rsquare_train.round(5),
print(lambd, " ", rsquare_train.round(5), "
18
                                   ", rsquare_train.round(5), "
                                                                               ", rsquare_test.round(5), "
                                                                                                                           ", meanse.round(5))
19 print(lambd, "
                                                                          ", rsquare_test.round(5))
```

```
1 R scores comparison
2 λ Training R2 Testing R2
3 10.0 0.67461 0.94087
4 1.0 0.67947 0.84675
5 0.1 0.69447 0.67329
6 0.01 0.71165 0.58528
7 0.001 0.71483 0.56252
```

Finally, please decide the best regularization parameter λ. (Note that: As a qualified data analyst, you must know how to choose model parameters, please learn about cross validation methods.)

```
1 from sklearn.model_selection import KFold
2 from sklearn.linear_model import Ridge
    from sklearn.model_selection import GridSearchCV
5 def cross_validation(X, y):
6
       Using k-fold to get optimal value of lambda based on R-squared.
8
9
      Parameters:
10
       X: features, IV.y: taget variable, DV.
11
13
      Return:
14

       lambdas = [10, 1, 0.1, 0.01, 0.001]
19
20
       grid_param = {"alpha": lambdas}
       grid = GridSearchCV(estimator=model,
                          param_grid=grid_param,
23
                           cv=kfold,
24
                           scoring="r2")
2.5
      grid.fit(X, y)
26
       alpha = grid.best_params_['alpha']
27
       return alpha
28
29
30 print('Optimal lamba should be ', cross_validation(X_train, y_train))
```

```
oldsymbol{1} optimal lamba should be oldsymbol{0.1}
```

```
C:\Users\oyrx\Anaconda3\lib\site-packages\sklearn\model_selection\_search.py:814: DeprecationWarning: The default of the `iid` parameter will change from True to False in version 0.22 and will be removed in 0.24. This will change numeric results when test-set sizes are unequal.

DeprecationWarning)
```

# **Problem 3 — Feature Selection**

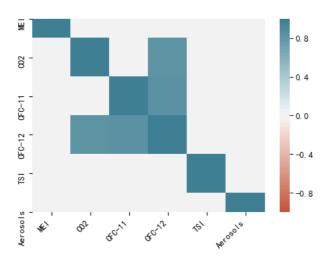

#### 1. Lesser variables

From Problem 1, you can know which variables are significant, therefore you can use less variables to train model. For example, remove highly correlated and redundant features. You can propose a workflow to select feature.

As mentioned in the first section and known significant variables (MEI, CO2, CDC-11, CDC-12, TST, Aerocols), a new correlation matrix can be introduced:

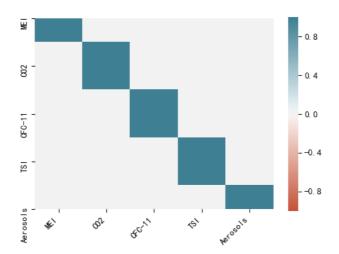

```
corr = df1[['MEI', 'CO2', 'CFC-11', 'CFC-12', 'TSI', 'Aerosols' ]].corr()
```

```
2 | high_corr = corr[np.abs(corr) > 0.5].fillna(0)
    corr[np.abs(corr) > 0.6].fillna('')
    plt.figure(dpi=96)
 5
   ax = sns.heatmap(
       high_corr,
 6
 7
        vmin=-1, vmax=1, center=0,
       cmap=sns.diverging_palette(20, 220, n=200),
9
        square=True
10 )
11 ax.set_xticklabels(
12
        ax.get_xticklabels(),
13
        rotation=45,
14
       horizontalalignment='right'
15 );
```

Thus, CFC-12 should also be removed(r>0.6) then we have:

```
corr = df1[['MEI', 'CO2', 'CFC-11', 'TSI', 'Aerosols' ]].corr()
    high_corr = corr[np.abs(corr) > 0.5].fillna(0)
 3 corr[np.abs(corr) > 0.6].fillna('')
 4 plt.figure(dpi=96)
 5 ax = sns.heatmap(
 6
      high_corr,
       vmin=-1, vmax=1, center=0,
 8
       cmap=sns.diverging_palette(20, 220, n=200),
9
        square=True
10 )
11 ax.set_xticklabels(
12
      ax.get_xticklabels(),
13
        rotation=45,
        horizontalalignment='right'
14
15 );
```

Now no redundant variables left.

### 2. A better model

Train a better model than the model in Problem 2.

```
1  X_lesser = dfl_train[['MEI', 'CO2', 'CFC-11', 'TSI', 'Aerosols' ]].to_numpy() # X: the features
2  y_lesser = dfl_train.iloc[:, [8]].to_numpy() # y: the results, lower case to emphasize the difference
3  X_test = dfl_test[['MEI', 'CO2', 'CFC-11', 'TSI', 'Aerosols' ]].to_numpy()
4  y_test = dfl_test.iloc[:, [8]].to_numpy()
5
6  #theta_lesser = closed_form_1(X_lesser, y_lesser)
7  theta_lesser = closed_form_2(X_lesser, y_train, cross_validation(X_lesser,y_lesser))
8  theta_lesser = np.array(theta_lesser)
9  formula = [str(theta_lesser.round(5).tolist()[i][0]) + ' * x' + str(i) + ' + ' for i in range(0, len(theta_lesser.round(5).tolist()))]
10  print('Thus our better model is: \ny = ' + ' '.join(formula).replace(' * x0', '')[:-3])
```

```
Thus our better model is: y = -0.02465 + 0.04909 * x1 + 0.0118 * x2 + 2e-05 * x3 + -0.00293 * x4 + -0.88807 * x5
```

C:\Users\oyrx\Anaconda3\lib\site-packages\sklearn\model\_selection\\_search.py:814: DeprecationWarning: The default of the `iid` parameter will change from True to False in version 0.22 and will be removed in 0.24. This will change numeric results when test-set sizes are unequal.

DeprecationWarning)

#### Significance:

Then remove x3 based on the new result:

```
X_lesser = dfl_train[['MEI', 'CO2', 'TSI', 'Aerosols']].to_numpy() # X: the features
y_lesser = dfl_train.iloc[:, [8]].to_numpy() # y: the results, lower case to emphasize the difference
X_test = dfl_test[['MEI', 'CO2', 'TSI', 'Aerosols']].to_numpy()
y_test = dfl_test.iloc[:, [8]].to_numpy()

theta_lesser = closed_form_1(X_lesser, y_train)
theta_lesser = np.array(theta_lesser)
formula = [str(theta_lesser.round(5).tolist()[i][0]) + ' * x' + str(i) + ' + ' for i in range(0, len(theta_lesser.round(5).tolist()))]
print('Thus our better model is: \n\ny = ' + ' '.join(formula).replace(' * x0', '')[:-3])
```

```
Thus our better model is:

y = -118.60162 + 0.06204 * x1 + 0.01069 * x2 + 0.08418 * x3 + -1.58444 * x4
```

```
1 | x1 | True

2 | x2 | True

3 | x3 | True

4 | x4 | True

5 | Name: P>|t|, dtype: bool
```

R2:

```
rsquare_train = score(y_lesser, predict(X_lesser, theta_lesser))
rsquare_test = score(y_test, predict(X_test, theta_lesser))
print(('R2\nTraining: {}\nTesting: {}').format(rsquare_train, rsquare_test))
```

```
1 R2
2 Training: 0.7336403428986276
3 Testing: 0.6328867941215394
```

# Problem 4 — Gradient Descent

Gradient descent algorithm is an iterative process that takes us to the minimum of a function. Please write down the iterative expression for updating the solution of linear model and implement it using Python or Matlab in gradientDescent function.

### **Cost and gradient functions**

```
def normalize(mtx: np.matrix, method="std"):
3
        To normalize a matrix
4
       Parameters:
6
          mtx: matrix
8
       Return:
9
       normalized matrix
10
11
12
        return (mtx - np.mean(mtx)) / np.std(mtx) # Normalization for faster convergence
13
14 def costFunction(X: np.matrix, y: np.matrix, theta: np.ndarray) -> float:
15
16
        To calculate cost given X, y, and theta in ndarrays.
17
18
       Parameters:
19
20
          X: features, IV.
         y: taget variable, DV.
theta: coefficients
21
23
       Return:
24
       cost: calculated cost
25
26
27
        # print(X.shape, np.array(theta).shape, y.shape) # for debugging
28
29
        m = len(y_train) # no. of training samples
30
        temp = X @ theta - y
31
        return np.sum(np.power(temp, 2)) / (2 * m)
32
33
34 def gradientDescent(X: np.matrix,
35
                         y: np.matrix,
36
                         theta: np.ndarray,
37
                         alpha: float = 0.001,
38
                         iterations: int = 10000,
39
                        norm: bool = True) -> np.ndarray:
40
       To find optimal theta given X, y, theta in ndarrays and alpha, iters in float.
41
42
43
       Parameters:
44
45
          X: features, IV.
        y: taget variable, DV.
theta: initial coefficients
alpha: learning rate, default by 0.001
iterations: an assigned number of iterations
norm: nomalization or not, default by True
46
47
48
50
      Return:
51
53
        theta: np.matrix, final theta
       J_history: np.ndarray, cost history
55
56
       X = (X, normalize(X))[norm] # normalization
58
        # print(X.shape, np.array(theta).shape, y.shape)
       m = len(y)
60
       J_history = []
61
        _theta = theta.copy()
62
       for i in range(iterations):
        error = X.T @ (X @ _theta - y)
63
           _theta -= alpha * 1 / m * error
65
            J_history.append(costFunction(X, y, _theta))
       # print(_theta, J_history)
66
       return _theta, J_history
```

### **Datasets**

```
features = ["MEI", "Co2", "CH4", "N20", "CFC-11", "CFC-12", "TSI", "Aerosols"] # Features

target = ["Temp"] # taget

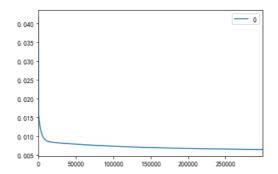

# Splitting into training and testing
year = 2006 # Specific year for splitting
train, test= dfl[dfl['Year'] <= year], dfl[dfl['Year'] > year]
X_train, X_test = train.get(features), test.get(features)
X_train, X_test = np.column_stack((np.ones(len(X_train)), X_train)), np.column_stack((np.ones(len(X_test)), X_test))
y_train, y_test = train.get(target), test.get(target)
X_train, X_test, y_train, y_test = np.mat(X_train), np.mat(X_test), np.mat(y_train), np.mat(y_test)
```

#### **Parameters**

```
# Define parameters
alpha = 0.01 # Learning rate
iterations = 300000 # The number of iterations
```

### Run

```
Initial cost: 0.047
Final cost: 0.006
Final theta(for normalized features): [0.205, 0.367, 1.474, 0.588, 0.584, -1.649, 1.033, -0.32, 0.201]
```

### Compare with theta(s)=0
